

# Fischer and Haworth projections

28 Jun 2025

## Fischer to Haworth projections

(linear  $\rightarrow$  ring)

1. Number the carbons from the carboxyl end of the molecule. Flip the molecule  $90^\circ$  to the right and draw the carbon backbone in a horizontal line. Keep track of the anomeric carbon (usually C1).
2. Draw the open ring structure of the molecule, placing the anomeric carbon at the right end of the ring. The groups at the top (originally left) of the rotated structure will point up, and the groups at the bottom (originally right) of the rotated structure will point down. Remember - “drop it right down, the rest are left up”
3. The hydroxyl (OH) group on the last chiral carbon will launch a nucleophilic attack on the carbonyl carbon to form the ring. Draw the bond between C1 and C5, and place the hydroxyl group on C1.
